a. In the Ottawa area and neighboring regions, Lyme disease can be transmitted by *Ixodes scapularis* ticks (blacklegged tick/deer tick) that are infected with *Borrelia burgdorferi*. Nymphs (most active in late spring and summer) are more likely to transmit Lyme disease compared to adult ticks (who don’t feed as long and are more easily noticeable). Dog and groundhog ticks do NOT carry and transmit Lyme disease. Individual tick pathogen testing is no longer available at the National Microbiology Laboratory (NML).

High risk bite
Tick attached > 24 hours with signs of engorgement (See Figure 1 & 2)

Time from tick removal
≤ 72 hours
Offer prophylaxis
Monitor x 32 days

> 72 hours
Prophylaxis not recommended
Monitor x 32 days

Low risk bite
Tick attached < 24 hours and flat (See Figure 1 & 2)

No Prophylaxis
Risk of transmission very low
Monitor x 32 days

DO not send serology in the context of prophylaxis

Known tick bite
Was it a blacklegged tick a AND acquired in “at risk” area b?

YES/POSSIBLE

NO

b. Ottawa and neighboring regions are considered “at risk” areas for Lyme disease. Local surveillance study reports around 1/3 of ticks tested were infected with *B. burgdorferi* (with site to site variability). Recreational trails, conservation areas/forests and the provincial park within the city of Ottawa had significantly higher tick densities than municipal parks. However, all wooded, bushy, or tall-grassed areas in Ottawa should be considered “at risk” (See Ref 2 & 3)

For other “at risk” areas:
- In Ontario: See risk map page 4
- In Quebec: See risk map page 5
- In Canada: See risk map page 5

C. Signs of early localized Lyme disease:
Generally presents within 7-14 days of tick bite, (range 3-32 days). Most patients (60-80%) present with a classic erythema migrans (EM) rash which consists of a single erythematous, expanding, > 5 cm rash +/- central clearing at the site of the tick bite. Rash can have many appearances (see Ref 8). This may be associated with arthralgia, myalgia, headaches and fever. A rash that does not expand and/or resolves within 24-48 h is highly unlikely to be EM. If a person develops evidence of early Lyme disease, they should consult a physician and receive appropriate antibiotic treatment (not prophylaxis) – See page 2.

Prophylaxis for Lyme disease – single dose
≥ 45 kg: Doxycycline 200 mg PO once
< 45 kg: Doxycycline 4.4 mg/kg/dose PO once (max 200 mg)
* There is no age restriction for the use of short courses of doxycycline. (see Ref 5)
* Can be given during pregnancy and lactation (see Ref 6)

*Can be given during pregnancy and lactation (see Ref 6)
TREATMENT OF EARLY LYME DISEASE

Suspected early localized Lyme disease
Generally presents within 7-14 days of tick bite, (range 3-32 days). Most patients (60-80%) present with a classic erythema migrans (EM) rash which consists of a single erythematous, expanding, > 5 cm rash +/- central clearing at the site of the tick bite. Rash can have many appearances (see Figure 3 and Ref 9). This may be associated with arthralgia, myalgia, headaches and fever. A rash that does not expand and/or resolves within 24-48 h is highly unlikely to be EM. A tick saliva hypersensitivity reaction is most likely in cases of rashes < 5 cm appearing within 72 hours of the tick bite (Not Lyme Disease and no treatment required).

Start empiric therapy
Treatment of EM results in rapid resolution of skin lesions within several days and almost always prevents development of later stages of Lyme disease.

Do not send serology in most cases of early Lyme disease

Time from tick detachment or potential exposure to ticks (through outdoor activities in “at risk areas”)

- > 32 days
- 3 – 32 days

Possible Early Disseminated Lyme Disease (see page 3)
- Skin: Multiple EM lesions
- Neuro: Cranial nerve palsies (especially CN7), aseptic meningitis, meningoradiculoneuritis
- Cardiac*: AV block, myopericarditis
- Joints: Arthritis (often mono/pauciarticular – large joints)
  * can sometimes occur < 32 days – more commonly after 1 month

Possible Late Lyme Disease
- Joint: Chronic, intermittent arthritis
- Neuro: peripheral neuropathy, encephalomyelitis (very rare)

PATIENT EDUCATION
Counsel patients on possible persistent symptoms after adequate treatment of Lyme disease.
Some patients may have prolonged, persistent non-specific symptoms such as fatigue, pain or headaches, in the convalescent period which gradually resolves and responds to symptomatic treatment.
Adequately treated early Lyme disease does not need ID referral

In general, serology is done in cases of extracutaneous Lyme disease or if tick was acquired in a non “at risk” area. In addition, some patients may not present with EM and clinical diagnosis may be more difficult. Consideration should be given to serologic testing at the initial visit and repeated at least 2 weeks later
Serologic testing is not sensitive in the first 2-4 weeks after infection and not useful in the diagnosis of early cutaneous Lyme Disease. If tick bite was acquired in Europe – MUST specify on requisition to test for European Lyme
Serology follows national and international recommendations involving two-tier serologic algorithm (at Public Health Ontario Laboratory).

Ottawa Lyme Algorithm (July 2022)

---

**Antibiotic** | **Dosage** | **Max dose** | **Duration**
--- | --- | --- | ---
Amoxicillin | 50 mg/kg/day PO div TID | 500 mg PO TID | 14 days
Doxycycline | 4.4 mg/kg/day PO div BID | 100 mg po BID | 10 days
Cefuroxime | 30 mg/kg/day PO div BID | 500 mg po BID | 14 days

Doxycycline potential adverse effects: photosensitivity (sun protection/sunscreen recommended). For short term use (< 14-21 days), visible teeth staining or enamel hypoplasia is unlikely to occur. Formulation covered by OHIP*: Doxycycline 100 mg tablets (can be quartered) and suspension (limited availability – verify with pharmacy first prior to ordering).

Allergies: For patients unable to take doxycycline or beta-lactam antibiotics – second line agent is azithromycin x 7 days Reference: 1 & 4
For Pregnancy: Use amoxicillin or cefuroxime (See Ref 6)
**MANAGEMENT OF DISSEMINATED LYME DISEASE**

**Suspected disseminated Lyme disease (clinical syndromes as below)**
- Following an unrecognized infected tick bite in an untreated patient, the Lyme disease bacteria can disseminate to other anatomic sites leading to other skin lesions (multiple EM), neurologic, cardiac or joint symptoms.
- Known tick bite or potential exposure would have typically occurred > 32 days prior but can be as early as a few weeks (cardiac).

### Skin
- Multiple EM lesions
- No need to send Lyme serology if lesions are typical
- Treatment: Similar treatment as single Erythema migrans (see page 2)

### Cardiac
- Typically occurs about a 1 month after initial infection (up to 40% do not recall an EM rash)
- Symptoms of Lyme carditis include: chest pain, dyspnea, edema, palpitations, syncope, exercise intolerance
- Asymptomatic patients do not have Lyme carditis
- - Send Lyme serology
- - If symptoms of carditis: do ECG, troponins
- - ID/Cardiology consult

### Neurological
- Headache, neck stiffness, facial nerve palsy
- - Send Lyme serology
- - If symptoms: do MRI/spine, LP
- - ID/Neuro Consult

### Joint
- Typically marked swelling of 1 joint (or < 5). Often affecting large joint (ie knee) and noted to be not as painful as expected with degree of swelling. Often lack of fever (but can be seen especially in children).
- - Send Lyme serology
- - Consider joint aspiration to rule out septic arthritis
- - ID/Rheumatology consult

### Lyme carditis suspected?
- AV block/conduction abnormalities, Lyme myocarditis or pericarditis
  - Treatment: Admit with continuous ECG monitoring if significant PR prolongation (PR > 300 ms), other arrhythmias or myopericarditis
    - Inpatient: Ceftriaxone IV
    - Outpatient: Doxycycline PO
  - Total duration: x 14-21 days

### Lyme neuroborreliosis suspected?
- **Meningitis, encephalitis, myelitis**
- **PN: Painful radiculoneuropathy, mononeuropathy multiplex, acute cranial neuropathies (especially CN VII, VIII > III, V, VI) radiculitis**
  - Treatment: Doxycycline x 14 days
  - - Facial palsy: Doxycycline x 14 days
  - - Meningitis or radiculopathy: Ceftriaxone IV and once improved and diagnosis confirmed, can complete course with doxycycline PO (total duration 14-21 days)
  - - ID/Neuro Consult

### Interpretation of Lyme Serology
- Lyme serology is very sensitive in the context of disseminated Lyme disease.
- Negative Lyme serology in this context rules out the diagnosis.
- If serology is drawn too early from onset of symptoms, then EIA may be reactive but Line Blot (Western Blot) is non-reactive. If indicated, resend another sample (convalescent) 2-3 weeks

### Co-infections
- If presents with high-grade fever or characteristic laboratories (thrombocytopenia, leukopenia, neutropenia +\- anemia, elevated indirect bilirubin and LDH) then consider testing for co-infection with *Anaplasma phagocytophilum* or *Babesia microti* which have been increasingly found in Ontario.
- Other tick-borne infections to consider also include Powassan virus disease and Borrelia miyamotoi disease.
Ontario Lyme Disease Map 2022
Estimated Risk Areas

Legend

- Estimated Risk Area
- Health Unit Boundary

While low, there is a possibility of encountering blacklegged ticks almost anywhere in the province, provided the habitat is suitable for blacklegged ticks (e.g., wooded or brushy areas).

From Public Health Ontario Lyme disease Risk Area Map
Lyme disease risk areas

Outaouais including Gatineau Park

Further areas are now considered at high risk (‘Risque significatif’). The following municipalities are considered at high risk (in orange): Gatineau (Aylmer, Hull, Gatineau, Vallée-de-la-Îlièvre) Bristol, Pontiac, La Pêche, Chelsea and Val-des-Monts. Most of Gatineau Park is now considered an area where there is high risk. In Cantley, the “risk is present” for Lyme Disease but not significant enough to warrant post-exposure prophylaxis.

Please consult an interactive map from the Institut national de Santé Publique Quebec (INSPQ) for more specific and up to date details on risk areas:

https://www.inspq.qc.ca/zoonoses/maladie-de-lyme.

Canada

This figure contains 5 cross-sections which display locations where the risk from tick bites is known to occur and is possible or for Lyme disease is possible. Circled hatched areas are locations where tick risk is known and are called risk areas. From:

Facts about Lyme disease in Ottawa

- Lyme disease is a complex infection with symptoms that can manifest within a few days (early Lyme disease) and as late as many months (early/late disseminated Lyme disease) following an infected tick bite.
- The overall risk of acquiring Lyme disease following an *I. scapularis* tick bite in a high-risk area is low and estimated to be around 2.2% [95% CI 1.2-3.9%] and when given appropriately, a single dose of doxycycline given as post-exposure prophylaxis, decreases the overall risk of progression to Lyme Disease to 0.2% [95% CI, 0-1] (Ref 4).
- Transmission < 24 hours of tick attachment is highly unlikely. Based on animal models, there is almost invariably a delay of at least 36 hours between the time of tick attachment and transmission of *B. burgdorferi*.
- Due to reassuring safety data, doxycycline can be given for short term use (< 14-21 days) in children of any age. (Ref 5)
- Treatment of early Lyme disease with appropriate antimicrobials is easy and effective.
- Prevention is key. Practice regular tick checks following outdoor activity. Wear appropriate light-colored clothing (to detect ticks more easily) and long sleeves/protective clothing, pants tucked into socks. Use insect/tick repellent (DEET, picaridin, IR3535, oil of lemon eucalyptus, p-methane-3,8-diol or permethrin) Remove attached tick promptly (within 24 hours) with fine-tipped tweezer.
