Ministry of Health

Novel Coronavirus (2019-nCoV)
Guidance for Primary Care Providers in a Community Setting

Version 2 – January 31, 2020

This fact sheet provides basic information only. It is not intended to take the place of medical advice, diagnosis or treatment.

There are a range of capabilities among primary care settings in Ontario and this document reflects a number of options that primary care providers may take depending on their capacity to safely use N95 respirators (fit test, training, supplies available) for patient examination and collection of specimens, as is recommended at this time.

Note: This guidance document was updated January 31, 2020 to reflect updates to the case definition for 2019-nCoV.

What you need to know

1. All primary care settings should follow Routine Practices (routine precautions) plus droplet and contact precautions.
2. All primary care settings should undertake active screening (asking questions) and passive screening (signage) of patients for 2019-nCoV and develop plans for referral where they are unable to conduct testing within their clinics.
3. Primary care providers should assess their capacity to safely conduct a clinical examination and collect specimens for a patient at risk of having 2019-nCoV.
   - Only primary care providers who can safely use and have access to N95 respirators should conduct detailed clinical examinations on a patient with a clinical and travel/exposure history consistent with the Person Under Investigation (PUI) definition. Providers must also have appropriate cleaning procedures.
4. Testing must happen in an appropriate setting - one that supports the safe use of N95 respirators during specimen collection.
   - Some primary care providers will have the capacity to test for 2019-nCoV.

5. Primary care providers must report to their local public health unit all patients suspected of having 2019-nCoV.

**Screening and Triage**

Primary care providers play an important role in supporting the response to suspected cases of 2019-nCoV. Primary care settings are being requested to conduct passive and active screening.

1. **Passive screening**

   - Signage should be posted on entry to the office and at reception areas for patients with symptoms to self-identify, perform hand hygiene, wear a procedure mask, and have access to tissue and a waste receptacle.
   - All patients should be instructed to cover their nose and mouth with a tissue when coughing and sneezing.
2. **Active screening at reception areas**

**Sample Screening**

Is the patient presenting with:

1. Fever, and/or new onset of cough or difficulty breathing, 
   AND any of the following:
2. Travel to/from Hubei Province (includes Wuhan), China in the 14 days before the onset of illness
   OR
   Close contact with a confirmed or probable case of 2019-nCoV
   OR
   Close contact with a person with acute respiratory illness who has been to/from Hubei Province (includes Wuhan), China in the 14 days before their symptom onset.

- Patients should be screened over the phone **before** scheduling appointments.
- Where patients present without phone screening, trained staff should screen patients upon entry using the above screening tool.
- Staff conducting screening should ideally be behind a barrier to protect from droplet/contact spread. A plexiglass barrier can protect reception staff from sneezing/ coughing patients.

3. **What to do if a patient screens positive by phone?**

- Where staff in the primary care office **have the ability** to safely use and has access to N95 respirators (e.g., fit tested, training, procedures, supplies), they may offer clinical assessment, examination, and testing (as indicated) in the their clinics. Patients should be given a procedure mask and placed in a room with the door closed on arrival to avoid contact with other patients in common area of the practice (e.g., waiting rooms). Clinicians should also:
  - Take a detailed history and conduct a clinical assessment to determine if the patient meets the case definition of a PUI.
• The primary care provider should contact their local public health unit to report the suspect case and discuss the most appropriate setting for testing. Options may include: testing facilitated by the local public health unit; testing in the primary care office (using an N95 respirator) and ensuring coordination of sample delivery to the Public Health Ontario laboratory; or referral to the nearest emergency department. All referrals to hospital should be made to a triage nurse.

• Decisions about place of testing are dependent upon the patient’s symptoms, their exposure history, and local resources for conducting testing.

• If patients are referred to hospital, the primary care provider should coordinate with the hospital, local public health unit and the patient to make safe arrangements for travel to the hospital that maintains isolation of the patient. Where the patient is able, they can drive themselves to hospital.

• Where the primary care provider is unable to safely use an N95 respirator (i.e., are not fit tested, do not have access to a supply of N95 respirator, appropriate procedures are not in place to support safe use):
  
  o The primary care provider should take a clinical history and travel/exposure assessment by phone to determine if the patient is a PUI. The primary care provider should then contact the local public health unit to report the individual as a PUI, determine whether testing is appropriate, and if so, a management plan for the safe clinical examination and testing of the patient.

4. What to do if a patient screens positive at the office?

• Where staff in the primary care office have the ability to safely use N95s respirators (e.g., fit tested, training, procedures, supplies). They may offer clinical assessment, examination, and possibly testing, in the primary care setting:
  
  o Patients should be instructed to wear a procedure mask (if tolerated) and be placed in a single room on arrival to wait for further assessment.
• Primary care providers should take a detailed history and clinical examination to determine if the patient meets the case definition of a person under investigation (PUI).

• Primary care providers should contact their local public health unit to report the patient and discuss the most appropriate setting for testing. Options may include: testing facilitated by the local public health unit; testing in the primary care office (using an N95 respirator) and ensuring coordination of sample delivery to the Public Health Ontario laboratory, or referral to the nearest emergency department. All referrals to hospital should be made to a triage nurse.

• If patients are referred to hospital, the primary care provider should coordinate with the hospital, local public health unit and the patient to make safe arrangements for travel to the hospital that maintains isolation of the patient.

  • Where the primary care provider is unable to safely use an N95 respirator (i.e., are not fit tested, do not have access to a supply of N95, appropriate procedures are not in place to support safe use) they should use a procedure mask and isolate the patient as above including providing a procedure mask for the patient to wear. The provider can conduct a clinical history and visual assessment while under contact/droplet precautions and maintaining a 2 metre distance from the patient.

  • The primary care provider should contact the local public health unit to report the PUI, and to discuss the most appropriate way for the patient to be clinical assessed and be tested, if warranted.

  • If patients are referred to hospital, the primary care provider should work with the hospital, local public health unit and the patient to make safe arrangements for travel to the hospital while maintaining isolation of the patient.

**Testing**

• At this time, primary care providers are not expected to conduct testing for 2019-NCoV. However, all primary care providers have a duty to report a patient who has or may have NCoV to the local public health unit.
• Primary care practices who can safely use N95 respirators (if available) and have the capacity to collect and send the appropriate specimens for 2019-nCoV to PHO, may test patients who they determine are a PUI.

• For more information about testing see the test information sheet.

5. **What to do if a patient has travel history to Hubei, China within the last 14 days but is asymptomatic?**

• Any asymptomatic patient with a relevant travel/exposure should be advised to monitor for symptoms. If they develop a fever, onset of a new cough or difficulty breathing within 14 days of their travel date, they should call their primary care provider, Telehealth Ontario or your local public health unit.

**Occupational Health & Safety and Infection Prevention & Control Advice for Primary Care Settings**

Within primary care settings, the ministry recommends the use of Routine Practices and Additional Precautions (contact, droplet) for screening of patients. These precautions include:

• use of gloves, gowns, procedure mask and eye protection

• hand hygiene

Primary care providers who can offer clinical examinations of patients who meet PUI criteria must use N95 respirators.

For more information please see: [PIDAC Routine Practices and Additional Precautions In All Health Care Settings](#)

**What is known about the 2019-nCoV**

Coronaviruses (CoV) are a large family of viruses that cause illness ranging from the common cold to more severe diseases such as Middle East Respiratory Syndrome
(MERS-CoV), Severe Acute Respiratory Syndrome (SARS-CoV), and 2019-nCoV. A novel coronavirus is a new strain that has not been previously identified in humans.

Coronaviruses are zoonotic, meaning they are transmitted between animals and people. Detailed investigations found that SARS-CoV was transmitted from civet cats to humans and MERS-CoV from dromedary camels to humans, likely through bat reservoirs. Several known coronaviruses are circulating in animals that are not infectious to humans.

On 31 December 2019, the World Health Organization (WHO) was informed of cases of pneumonia of unknown etiology in Wuhan City, Hubei Province in China. A novel coronavirus (2019-nCoV) was identified as the causative agent by Chinese authorities on January 7, 2020.

Common signs of infection include fever, respiratory symptoms such as cough, shortness of breath and breathing difficulties. In more severe cases, infection can cause pneumonia, kidney failure and even death.

Recommendations to prevent infection spread include performing hand hygiene (either use of alcohol-based hand rub or hand washing with soap and water), respiratory hygiene and cough etiquette (e.g., covering mouth and nose when coughing and sneezing, using tissues to contain respiratory secretions).

As of January 27, 2020, two cases of 2019-nCoV have been announced in Ontario in a couple who had recently returned from Wuhan, China. While it is anticipated that we may see additional cases with travel history to the impacted region, the overall risk to the community remains low.

At this time:

- Almost all cases have direct or indirect epidemiological link to Hubei province, China.

- Effective infection prevention & control measures are in place across Ontario’s health system.

Primary care providers in Ontario should consider the possibility of 2019-nCoV infection in persons who present with fever and respiratory symptoms and travel to/epidemiological link to Hubei province within the past 14 days (see case

For more information

If you have any questions, please consult the ministry’s website on 2019-nCoV or contact your local Public Health Unit.
General Advice to Primary Care Providers

There are several things that primary care providers can do to prevent themselves, their staff, and patients from becoming sick with this virus:

• Have procedure masks, tissues and Alcohol Based Hand Rub available to patients and staff in clinics/offices.

• Review infection prevention and control/occupational health and safety policies and procedures with staff.

• Post signage on clinic/office doors and reception areas informing persons to self-identify if they are experiencing fever, acute respiratory illness, and have a travel history to Hubei province, China in the last 14 days since onset of illness or contact with a person who has the above travel history and is ill (see screening procedures above).
